

A llama is the central figure, wearing red 3D glasses. The background is dark with a subtle grid pattern.

AI Gaming · Team Cyber Tesla · NeuroBridge.SI Baku 2026

PlayerOne

An AI playtester. It plays your game, catches the bug, and files the report with proof. A free local AI does the playing. A big AI only does the judging.

roaring-alfajores-8a941a.netlify.app · github.com/nijathatamli/AI-hakaton

Value for the user

Small studios ship bugs because nobody has time to replay the game

Indie teams of 1 to 15 people build PC games in Godot, Unity and Unreal with no QA team. Soft-locks, crashes and broken counters reach players, and the first report is a one-star review with no steps to reproduce.

Manual testing

Slow and repetitive. Nobody replays level 3 for the hundredth time after every build.

Hiring QA

Too expensive for a small team, and still slow to turn around.

A big AI playing

Reads a full screenshot every move. We measured 67,000 to 85,000 tokens per minute of play.

How it works

Split the brain. Cheap hands, smart judge.

free · on your PC

Play

A local vision AI or our free bot plays the game with real keys and mouse. Any engine, no SDK.

exact · zero tokens

Watch

Reads the engine console, catches crashes, hangs and softlocks, records the last 12 seconds.

your AI · tiny digests

Judge

Claude, Codex or Gemini read a 45 KB summary, decide what is a real bug and write the ticket.

The prototype

Pick a game. It
knows how to
play.

PlayerOne recognises the game, suggests the controls, and you approve exactly what the AI may press. It never touches Alt+F4 or anything outside the game. F8 stops it anywhere.

Desktop app for Windows, macOS and Linux.
Released as v0.2.3 with installers for 5 targets.

What the AI **actually** does

Plays from pixels

A vision model reads each frame and chooses keys, mouse look and clicks from the approved controls. When it gets stuck it turns away and tries something else.

Works out the controls

Recognises the game by name or by looking at the screen, and picks a control layout: first-person, platformer, top-down and more.

Judges with evidence

The big AI gets the console errors and a contact sheet of the seconds before each incident, decides if it is a bug, and steers the player.

Plugs into your agent

One click connects Claude Code, Codex or Gemini CLI through MCP. Your agent directs, our local model plays.

What a report looks like

Proof, not "it broke somewhere"

Every bug comes with the engine error and stack trace (main.gd line 148), the inputs that led there, this 36 KB picture of the seconds before it, and a 14 KB clip.

Quality testing

We broke our own game on purpose

Five planted bugs plus a clean build, one minute of real play each, three players. 18 runs, all logs in the repo.

Bug	Random keys	Free bot	Local AI
Soft-lock	34s	15s	39s
Script error	missed	12.5s	missed
Crash	missed	18s	missed
Freeze	missed	20s	missed
Coin counter	missed	missed	missed
False alarms	0	0	0

What broke, and what we did

PlayerOne froze with a frozen game. Capture now has a 1.5s deadline.

13 false alarms. Now it tries every control before calling it stuck. Down to 0.

Still open: the coin counter bug needs a smarter AI to see it. The 3B model is too slow to explore.

Compared with today

The same minute of testing,
96% fewer tokens

70K

tokens a big AI spends playing one
minute itself

2,975

tokens it spent judging that
minute through PlayerOne

12-20s

to catch a crash, a hang or a
script error, with the report
already written

Business model

Free users cost us **almost nothing**. The game and the AI run on their PC.

Who pays and for what

1

Free

Hooks every indie dev. Local AI, crash and console capture. Costs us nothing to serve.

2

Connect, monthly

Their own Claude, Codex or Gemini key judges. They pay the model, we keep the subscription. Cloud history and dashboard.

3

Studio, per seat

Shared reports and a playtest in CI after every build. Where team budgets live.

4

Credits

Our hosted judge for people with no key. Priced on the tokens we measure, about 180k per hour of play, plus margin.

Getting customers

Godot, Unity and itch.io communities, game jams, and Baku studios first. Free is the funnel: every report says "found by PlayerOne".

Why we win

Testing tools that need an SDK cost weeks to integrate. A big AI playing alone costs 70k tokens a minute. We need neither.

Already live

Accounts, plans, usage metering on Supabase. Stripe webhook. Website sign-in. Installers for 5 platforms.

Feasibility

Runs today, on hardware people
already own

Data needed

None. No training data and no game source code. It works from the screen and the engine console.

Running cost

Playing is free on the user's PC (a 3B model on a laptop GPU, under 1.5 s a move). The judge reads about 3k tokens per minute.

Next step

Signed builds, Unity and Unreal log probes on real projects, and a 30-day pilot with three Baku studios.

Originality and next step

No SDK. No engine plugin. **Any game on screen.**

Other AI testing tools need engine integration and run the expensive model on every frame. PlayerOne attaches to any window, trusts the engine console first, and only sends the big model a compressed digest.

Next 30 days

Pilot with three Baku indie studios on their real games and measure bugs found per build.

Product

Unity and Unreal log probes on real projects, signed builds, a small overlay so you can watch the AI play.
